

Observations (from visuals)

1. Gender: Females had a much higher survival rate than males.
 - Female survival rate: X% (compute with code)
 - Male survival rate: Y%
2. Pclass: 1st class passengers had the best survival; 3rd class the worst.
 - Survival by class: (show means)
3. Age: Younger passengers, especially children, had higher survival.
 - Median age survivors vs non-survivors.
4. Fare: Higher fare correlated with higher survival (fare often a proxy for class).
5. FamilySize: Very large families had lower survival; small families and those alone had better survival (show numbers).
6. Embarked: Passengers embarked from 'C' had higher survival proportion (report exact %).
7. Titles: Titles such as 'Mrs', 'Miss', 'Master' show different survival rates — Title captures social status and correlates with survival.

Final summary

Using EDA on the Titanic dataset, gender, passenger class, fare, and age are the most predictive factors of survival. Women and first-class passengers had the highest survival rates. Fare and class are correlated — passengers paying higher fares tended to survive more. Children had relatively higher survival probability compared to older adults. Family size and port of embarkation also show differences in survival rates. These findings suggest that social status and demographic factors were critical determinants of survival during the Titanic disaster.
